

# Checked boxes? Check kidneys.

Early kidney disease often has no symptoms. In fact, many people are not diagnosed until just before their kidneys fail. That is why it's so important to test your patients who are at risk for kidney disease. Two simple checks will help you detect:

1. Estimated glomerular filtration rate (eGFR) and
2. Albumin-to-creatinine ratio (UACR).

Prevention is possible, and early detection and management can delay disease progression. Help enhance your patients' length and quality of life by checking their kidneys.
